ABSTRACT

Background: Quercetin is one of the main flavonoids, overall distributed in plants. The antioxidant capacity of quercetin is several times vitamin E and glutathione. This systematic review and meta-analysis of randomized controlled trials were performed to determine the effect of quercetin on oxidative stress (OS) markers. **Methods**: A literature search was conducted in PubMed, ISI Web of Science, Scopus, and Google Scholar to February of 2021. Meta-analysis was conducted on 8 eligible RCTs containing a total of 668 participants. The weighted mean difference (WMD) with 95% confidence intervals (CIs) was calculated for a pool effect size of Malondialdehyde (MDA), Total Antioxidant Capacity (TAC), and Ferric Reducing Ability of Plasma (FRAP). Subgroup analyses were performed based on intervention duration and dosage. The heterogeneity of studies was examined by Cochran's Q test and I-squared (I^2) statistic. **Results**: Effect sizes from 668 participants based on the random effect model showed that quercetin supplementation had no significant effect on TAC and MDA compared to the control group. The analysis illustrated that quercetin supplementation significantly increased FRAP in adults (WMD = -0.159 mmol/l, 95% confidence interval (CI):-0.178, -0.141, $P \leq 0.001$). **Conclusions**: The finding of the current study showed that quercetin supplementation had no significant effect on TAC levels, although it significantly increased FRAP levels in adults. Also, MDA level did not markedly change. It has needed to conduct clinical trials with more quality and bigger sample sizes to verify the positive impact of quercetin on stress oxidative marker.

Keywords: *Quercetin; Oxidative stress; Malondialdehyde; Total antioxidant capacity; Ferric reducing ability of plasma*

Introduction

Oxidative stress (OS) is a potential injurious mechanism to human health. It plays a predominant role in the origination of reactive oxygen species (ROS) (van't Erve, 2018). ROS

This paper should be cited as: Ahmadi Vasmehjani A, Yaghoubi F, Darabi Z, Abdollahi N, Sangsefidi ZS, Hosseinzadeh M ***The Effect of Quercetin on Stress Oxidative Markers: A Systematic Review and Meta-Analysis of Randomized Controlled Clinical Trials.*** *Journal of Nutrition and Food Security (JNFS)*, 2022; 7(4): 548-561.

reacts with proteins, membrane lipids, and nucleic acids directly which causes disrupting cellular function. Finally OS can designate to pathological diseases, such as cancer, neurological disorders, atherosclerosis, hypertension, ischemia/perfusion, diabetes, acute respiratory distress syndrome, idiopathic pulmonary fibrosis, chronic obstructive pulmonary disease, and asthma (Birben *et al.*, 2012, Sepidarkish *et al.*, 2019, Sties *et al.*, 2018, van't Erve, 2018). Any other way, cell defense systems have integrated antioxidant systems, which consist of enzymatic and non-enzymatic antioxidants. Enzymatic antioxidants include superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GPX) (Linke *et al.*, 2005, Sties *et al.*, 2018). OS occurs when the natural production of ROS cannot be balanced by the anti-oxidative capacity of tissues (Barja, 2013). Many studies have focused on strategies to reduce OS with the goal of bettering health. Diet modification or utilization of supplementation are used to change antioxidants levels (van't Erve, 2018). One of the must usually ways for scavenger of ROS is Quercetin. Antioxidant capacity of quercetin is several times that of endogenous antioxidants consisting of vitamin E and glutathione (Boots *et al.*, 2011). It is one of the main flavonoids, overall distributed in (edible) plants (Egert *et al.*, 2009). Onions, kale, unpeeled apples berries, citrus fruits, and tea (Camellia sinensis) are affluent sources of quercetin (Brüll *et al.*, 2015). Some studies have shown that quercetin has manifested diversity of bioactive effects, such as antioxidant, anti-inflammatory, antimicrobial, antibacterial, and vasodilatory actions (Bazzucchi *et al.*, 2019, Brüll *et al.*, 2015, Egert *et al.*, 2009). In addition it has been realized to exert anti-aging, antithrombotic, anti aggregatory, and vasodilatory effects (Riva *et al.*, 2019). Some randomized controlled trials (RCTs) have examined the effects of quercetin on OS markers in diverse population, whereas the results are disagreed (Egert *et al.*, 2008, Scholten and Sergeev, 2013).

To the best of the authors' knowledge, there is no systematic review or meta- analysis study to assess the impact of quercetin administration on the OS markers in human. Thus, this meta-analysis aims to summarize the present evidence of RCTs on the effects of quercetin supplementation on OS markers among diverse population.

Materials and Methods

Protocol and search strategy: The protocol of the current study was registered in the international prospective register of systematic reviews (PROSPERO) database (http://www.crd.york.ac.uk/PROSPERO), with registration code of CRD42020219056. This review was performed based on Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) checklist (Liberati *et al.*, 2009). Medical electronic databases, including Scopus, Web of Science and PubMed, and Google Scholar were searched up to 15th Februay 2021. Medical Subject Heading (MeSH) terms and non-MeSH terms were applied to the effect of quercetin on oxidative stress markers. The following keywords were used to search with consideration of the wide range of synonyms used in literature. "Quercetin", "OS", "Malondialdehyde", "Thiobarbituric Acid Reactive Substances", "oxidative mediators", "OS markers", "Superoxide Dismutase", "Glutathione Peroxidase", "Catalase", "Glutathione", "GSH", "Glutathione Reductase", "total antioxidant capacity", "TAC", "Oxygen Radical Absorbance Capacity", "ORAC", "total oxidant status", and "F2-Isoprostanes". The study also examined the citation lists of review articles, correlated publications, and selection studies references to find pertinent studies. The results from search in different databases were mixed, and duplicates were removed.

Inclusion criteria:

1. Randomized controlled trials parallel or cross-over either drug or placebo design
2. Studies that investigated the effects of quercetin supplementation on OS parameters
3. Studies that implement sufficient data on OS parameters at baseline and at the end of the intervention in both quercetin and placebo groups to identify the difference in mean values with 95% confidence intervals (CIs).

[DOR: 20.1001.1.24767417.2022.7.4.5.0]
[DOI: 10.18502/jnfs.v7i4.11065]

4. Participants aged ≥18 years
5. Presented the prescribed dosage

Exclusion criteria:

1. Experimental studies, in vitro studies, case reports, observational studies, review articles, letters to the editor, and editorials were excluded from this meta-analysis.

2. Studies without control group also, in which other interventions were used along with quercetin supplementation were excluded from this meta-analysis.

Study selection: After removing duplicates, title and abstract screening was independently conducted by two reviewers (Ahmadi Vasmehjani A and Darabi Z), then relevant full texts were investigated and authors were contacted for those were unavailable and unclear.

Data extraction: The following data from each study was extracted: the author's name and the year of publication and country of origin; property of the participants (age, gender), duration of trial, RCT design, health status of participants; sample size (experimental group/controlled group); the duration of intervention; dosage of intervention; and the mean and standard deviation for major outcome. Data extraction was done by two investigators, independently (Ahmadi Vasmehjani A and Darabi Z) using a designed form according to the inclusion and exclusion criteria.

Risk of bias assessment: The quality assessment of selected RCTs was doing via the Cochrane Collaboration risk of bias tool based of random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete data, and selective reporting (Lorzadeh et al., 2019).

Data synthesis and analysis: The effects of quercetin supplementation on the changes of the following outcomes were calculated; MDA, TAC, and Ferric Reducing Ability of Plasma (FRAP). The data were pooled to determine the effect size via weighted mean differences (WMDs) with 95% CI. The random-effects model was used to calculate the WMDs with 95% CIs for conducting the meta-analysis. The statistical heterogeneity of included studies was assessed by the Q test and I^2 statistics. Statistical difference in heterogeneity existed if P-value < 0.1 and I^2 is greater than 50% (Higgins and Thompson, 2002). To identify the possible sources of heterogeneity in the included studies, sub-group analysis was performed.

Funnel plot and asymmetry tests, including Begg's rank correlation test and Egger's regression test were used for assessment of potential publication bias. Sensitivity analysis was conducted to examine effect of any study on the overall effect size. All of the analyses were performed using STATA version 14.0 (Stata Corp., College Station, TX, USA). A P-value < 0.05 was considered to be statistically significant unless otherwise specified.

Study selection: Flow chart of studies selection process is presented in **Figure 1**. According to the search designs from electronic medical databases, 1677 articles were found. 1580 article reminded after removing of duplicated. Eighteen article were removed for animal and cell line studies (n=1334), observational studies (n=79), review studies (n=60), clinical trials not about quercetin on OS (n=29), other articles (n=78). Eventually, 8 eligible studies included in this meta-analysis.

Quality assessment of the studies: The assessment of quality for the included articles is summarized in **Table 1**. Briefly, all studies were categorized as low risk of bias for incomplete outcome data, random sequence generation, selective reporting, and blinding of participants and personnel. Two studies were considered low risk of bias for allocation concealment and the remaining did not express any method for allocation concealment, so were regarded as unclear risk of bias. Blinding of outcome assessment was unclear in five studies. Five included studies were at least 1 of the 6 key domains unclear risk of bias, thus the overall quality was considered to be unclear and two studies were for all key domains low risk of bias, therefore their overall quality became low risk of bias.

[DOR: 20.1001.1.24767417.2022.7.4.5.0]
[DOI: 10.18502/jnfs.v7i4.11065]

Characteristics of studies: The details of the 8 included studies are presented in **Table 2**. Studies were listed based on the following information: country, age(y), gender, sample size (intervention), RCT design, intervention name, quercetin dosage, name control, duration, outcome, and health status of participants. Studies were published from 2007 to 2020 and sample size ranged from 8 to 668 participants. Cross-over design was in two studies. The intervention duration in the trials was between 1 to 84 days. The dose of quercetin in the intervention groups was from 500 to 2000 mg/day. Three and four studies were conducted in Iran and USD, respectively, and one study in Netherlands.

Results

Effect of quercetin supplementation on TAC level: Overall, 3 clinical trials examined the effect of Quercetin supplementation on TAC. The analysis demonstrated that quercetin supplementation had a no significant effect on TAC levels (WMD = 0.37 mmol/l; 95% confidence interval CI: -0.380, 0.454 mmol/l P = 0.864) and there was a significant heterogeneity between studies (Q statistic = 8.34, Cochrane Q test, P = 0.015, I^2 = 76%, **Figure 2**).

Effect of quercetin supplementation on MDA: Four studies assessed the effect of quercetin supplementation on MDA and the meta-analysis showed no significant effect in the MDA level (WMD = 0.12 mmol/l; 95% confidence interval (CI): -0.106, 0.345 mmol/l; P = 0.298]. However, heterogeneity was low between studies (Q statistic = 1.62, Cochrane Q test, P = 0.654, I^2 = 0%, **Figure 3**).

Effect of quercetin supplementation on FRAP: Three studies were included in the meta-analysis. The analysis illustrated that quercetin supplementation significantly increased FRAP in adults (WMD = -0.159 mmol/l, 95% confidence interval (CI): -0.178, -0.141, $P \leq 0.001$). However, heterogeneity was low between studies (Q statistic = 2.6, Cochrane Q test, P = 0.272, I^2 = 23.1%, **Figure 4**).

Sensitivity analysis and publication bias: The removal of the studies, one by one, did not considerably change the effect of quercetin consumption on TAC, MDA or FRAP. Moreover, modifying the correction coefficient, using 0.2 and 0.8 did not change the outcomes.

Although a slight asymmetry was seen in Begg's funnel plots. There was no evidence for the attendance of publication bias using statistical asymmetry tests: TAC (Begg's test, P = 1.00; Egger's test, P = 0.834), MAD (Begg's test, P = 1.00; Egger's test, P = 0.30), FRAP (Begg's test, P = 1.00; Egger's test, P = 0.340). Results of funnel plot for Begg test are respectively shown in **Figure 5**, **6**, and **7** for TAC, MDA, and FRAP.

Discussion

The finding of the current study showed that quercetin supplementation had no significant effect on TAC levels, but the overall result represented a significant increase in FRAP levels in adults. However, heterogeneity was not high between these studies. Also, MDA level did not markedly change with this supplementation. However, sensitivity analysis did not represent any sensitivity to the included studies.

OS plays a key role in the pathogenesis of many common diseases, such as diabetes, cardiovascular

[DOR: 20.1001.1.24767417.2022.7.4.5.0]
[DOI: 10.18502/jnfs.v7i4.11065]

diseases, obesity and cancer (Halliwell, 2000). It might account for progressive damage DNA, proteins, and lipids. In fact, it is produced in the body following ageing processes or during an acute inflammatory response. Therefore, there is a link between OS and inflammation (Basu, 2008, Finkel, 2003).

Many surveys have been carried out over the effect of quercetin on different factors which have shown controversial results. A recent systematic review and meta-analysis assessed the impact of quercetin supplementation on inflammatory markers and lipid profiles among patients with metabolic syndrome and related disorders, which demonstrated that quercetin supplementation considerably diminished total-cholesterol, low density lipoprotein cholesterol (LDL-c), and CRP levels, while did not affect triglycerides, high density lipoprotein cholesterol (HDL-c), IL-6, and TNF-α (Tabrizi *et al.*, 2020). In contrast, another meta-analysis did not report any relevant effects of quercetin on peripheral CRP, IL-6, and TNF-α, although circulating CRP significantly decreased (Ou *et al.*, 2020). The results of a recently published meta-analysis showed that the effect of quercetin on plasma lipid profiles, blood pressure, and glucose levels significantly reduced both systolic and diastolic blood pressure, but not in other markers of lipid profiles and glucose concentrations (Huang *et al.*, 2020).

Also, the effect of quercetin, as an adenosine-receptor antagonist, on the reduction of OS was evaluated via inhibition of the enzyme xanthine oxidase (XO) that did not change after repeated sprints (Abbey and Rankin, 2011).

Another survey has assessed the impact of quercetin on endothelin-1 and OS after nitric oxide production by the measurement of S-nitrosothiols, nitrite and nitrate concentrations and F2-isoprostanes, respectively. Although, urinary endothelin-1 concentration significantly decreased by quercetin, the level of plasma or urinary F2-isoprostane concentrations did not change markedly, and showed no significant effect of quercetin on OS (Loke *et al.*, 2008). The effect of quercetin on plasma antioxidant levels and increase in exercise-induced oxidative damage in forty athletes has been investigated through measurement of F2-isoprostanes, FRAP, nitrite, trolox equivalent antioxidant capacity, and CRP. Despite demonstrating in-vitro potent antioxidant actions of quercetin in previous studies, the results of this study represented no protection of chronic quercetin ingestion from inflammation and exercise-induced OS (McAnulty *et al.*, 2008).

Subsequently, these controversial results can be impacted by several factors, including different dosage and duration of supplementary treatment, sample size of surveys, diverse status of subjects' health in the beginning and initial levels of OS markers (Haghighat *et al.*, 2013, Sangsefidi *et al.*, 2020). A previous study has shown that F2-isoprostanes and FRAP differed significantly between the obese and normal weight subjects, although subgroup analyses for body mass index (BMI) did not represent any significant difference (Shanely *et al.*, 2010). The role of polyphenols can change between antioxidants and pro-oxidants according to the concentration of polyphenols and free radical sources, which consequently can act as either anti-inflammatory or pro-inflammatory compounds (Cao *et al.*, 1997, Di *et al.*, 2008).

The role of ROS and its abnormal regulation in pathological conditions, encompassing inflammation, cancer, angiogenesis, atherosclerosis, and aging is undeniable (Gibellini *et al.*, 2010). On the other hand, protective role of quercetin against inflammation, apoptosis and OS has been proved in many studies (Ghosh *et al.*, 2009, Harwood *et al.*, 2007, Liu *et al.*, 2010). There are several mechanisms by which quercetin can link to growth, cell survival, apoptosis, and inflammation, such as protein kinase B, mitogen-activated protein kinases (MAPKs), phosphoinositol-3-kinase, NK-κB, and COX-2 (Granado-Serrano *et al.*, 2006, Lee *et al.*, 2007, Raja *et al.*, 2017).

Using advanced search strategy, lack of linguistic restrictions in the search process, quality assessment basis on the Cochrane criteria as well as low heterogeneity and low publication bias were among the advantages of this study. On the other hand, there are some limitations, including low

[DOR: 20.1001.1.24767417.2022.7.4.5.0]
[DOI: 10.18502/jnfs.v7i4.11065]

number of included trials and low subgroup analysis according to duration and dosage of supplementation.

Conclusion

As a result, the current study represents that the supplementation with quercetin had no significant effect on TAC and MDA levels but increased FRAP. More surveys with bigger sample sizes and high quality are needed to illustrate the effective role of quercetin in the reduction of ROS.
